# The Journey So Far

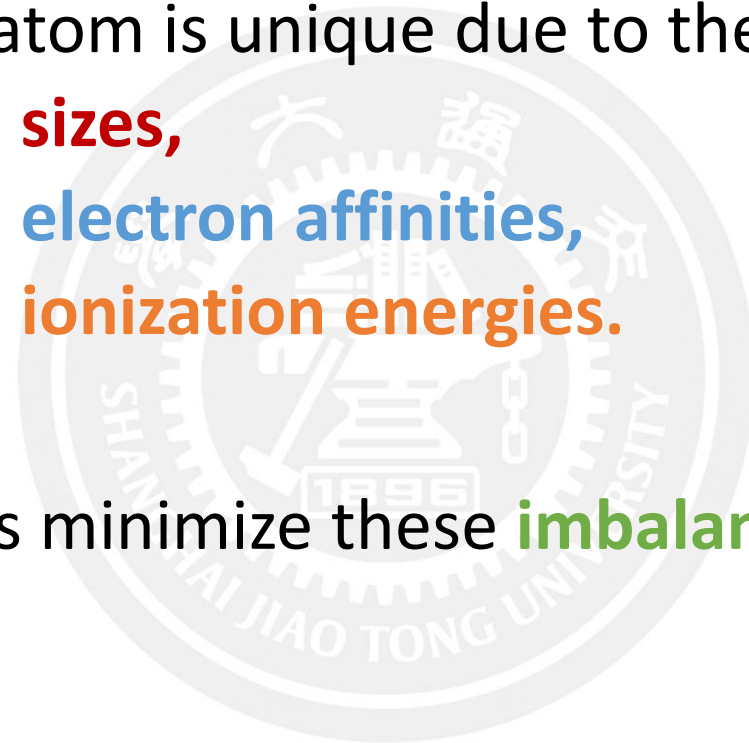

# Bonds between Atoms

Each atom is unique due to their differing:

- **sizes,**
- **electron affinities,**
- **ionization energies.**

Atoms minimize these **imbalances** by forming bonds.

# Bonds between Atoms

Atoms strive to **fill** their outer shells with electrons just like a noble gas does.

In a generalized way, atoms can achieve satisfaction by forming two types of bonds: ionic and covalent.

**Ionic** is **gaining** and **losing** electrons.

**Covalent** is **sharing** electrons.

The resulting bond is **lower** in energy than the separate atoms.

If **electrons transfer** from one or more atoms, the entire compound is held together by **electrostatic attractions** between all the ions.

This attraction is called an **ionic bond**.

The new ionic partnership is lower in energy than the separate atoms.

Binary ionic compounds form between **metals** and a **non-metallic** element.

Cations and anions stack into alternating, oppositely charged ions that line up in three dimensions.

Figure 23.1  
Atkins, Chemical Principles: The Quest for Insight, 7e

# Non-metals

Nonmetals **rarely lose electrons** because their **ionization** and **electron affinity** energies are too high.

Instead, nonmetal atoms **acquire electrons** to fill their outer shell.

**noble-gas core**

Ion	Configuration
$\text{N}^{3-}$	$[\text{Ne}]$ or $2s^22p^6$
$\text{O}^{2-}$	$[\text{Ne}]$

# Lewis Dot Notation

A **single dot** represents a **valence electron**, the *outermost electron in the last shell*, in the atom.

A **pair of dots** represents two paired electrons sharing an orbital.

Each symbol is thought of as having four sides, a north, south, east, and west position, where valence electrons are shown as dots.

# Lewis Dot Notation

An ionic formula starts by **removing valence electrons** from the metal and **transferring** them to the **nonmetal atom** to complete its valence shell.

The **calcium** atom loses its two valence electrons.

Each **chlorine** atom has a vacancy for one electron, therefore it forms one bond.

**Two** chloride ions ( $\text{Cl}^-$ ) ***balances the charge*** for **each** calcium ion ( $\text{Ca}^{2+}$ ) resulting in the formula  $\text{CaCl}_2$ ; the overall charge is zero.

There are **no**  $\text{CaCl}_2$  molecules, only **crystals** of three-dimensional arrays of  $\text{Ca}^{2+}$  and  $\text{Cl}^-$  ions held by the vast array of opposite charges spread throughout the crystal—hence  $\text{CaCl}_2$  is called a **formula unit**.

# Crystal Formation

**Crystal formation** starts when large numbers of oppositely charged ions, **rush** together, releasing large amounts of energy.

Figure 3H.28  
Atkins, *Chemical Principles: The Quest for Insight*, 7e  
W. H. Freeman & Company, © 2016 by P. W. Atkins, L. L. Jones, and L. E. Laverman

# Crystal Formation

Figure 2A.5

Atkins, *Chemical Principles: The Quest for Insight*, 7e

W. H. Freeman & Company, © 2016 by P. W. Atkins, L. L. Jones, and L. E. Laverman

A **crystal** of sodium chloride has lower energy than separated sodium and chlorine atoms.

Formation of the solid takes place in three steps:

1. Sodium atoms release electrons.
2. These electrons attach to chlorine atoms.
3. Newly formed cations and anions clump together as a crystal.

# Crystal Lattice Formation: Energy

# Lattice Energy

**Lattice energy** is a "**global**" characteristic of the **entire** crystal, a net lowering of energy in the entire crystal (once the cations and anions clump together as a crystal).

A **high lattice energy** value indicates **a stronger ion pair**, which produces a more tightly bonded solid.

**Coulomb's potential energy** measures the strength between individual ion pairs.

**Note:** Lattice energies describe the dispersion of a crystal into gaseous ions and are therefore **always positive**.

	Lattice energy / $\text{kJ}\cdot\text{mol}^{-1}$
LiI	759
NaI	700
KI	645
RbI	632
CsI	601

# Short Quiz

Which of the following compounds would be expected to have the strongest ionic bonds?

- A. KI
- B. NaI
- C. CsF
- D. LiF**

**Smaller ions** have higher effective nuclear charges and are therefore bound together more tightly, which produces **higher lattice energies**.

	Lattice energy / $\text{kJ}\cdot\text{mol}^{-1}$
LiI	759
NaI	700
KI	645
RbI	632
CsI	601

# Macroscopic Consequences

The **strong attraction** (Coulomb's potential energy) between oppositely charged ions accounts for the typical properties of ionic solids:

- **high melting points** and
- **brittleness**.

Figure 2A.6

Atkins, *Chemical Principles: The Quest for Insight*, 7e

W. H. Freeman & Company, © 2016 by P. W. Atkins, L. L. Jones, and L. E. Laverman

## Measure of the ion–ion force

$$E_{P,12} = \frac{z_1 z_2 e^2}{4\pi\epsilon_0 d_{12}}$$

- $e$  is the fundamental charge (the absolute value of the charge of an electron)
- $z_1$  and  $z_2$  are the charge numbers of the two ions, e.g., +2, +1, -1...
- $d_{12}$  is the distance between the centers of the ions
- $\epsilon_0$  is the vacuum permittivity

As  $d \uparrow$   $E \downarrow$

**Covalent bonds** form between **two non-metals** that **do not form ions**.

The nature of nonmetal bonds *puzzled* scientists until 1916, when **G. N. Lewis** published his explanation.

A brilliant insight, before anyone knew anything about quantum mechanics

1 Shared electron pair

Atkins, *Chemical Principles: The Quest for Insight*, 7e  
W. H. Freeman & Company, © 2016 by P. W. Atkins, L. L. Jones, and L. E. Laverman

# Lewis' Octet Rule

Lewis called this principle the **octet rule**, reaching a **noble-gas configuration**.

**Ionic bonds** form when one element **loses** electrons and the other atom **gains** electrons, until both atoms reach a **noble-gas configuration**.

Figure 2A.8  
Atkins, *Chemical Principles: The Quest for Insight*, 7e  
Prof. P. Motta/Science Source

**Covalent bonds** form by atoms **sharing** electrons until they reach a **noble-gas configuration**.

# Covalent Bonds

A fluorine atom can achieve an octet by accepting a share in an electron from another fluorine atom.

The **octet** (or duplet) shows **lines** (bonding pairs) and **dots** (lone pairs).

JOINT INSTITUTE  
交大密西根学院

$$\begin{array}{ccccccc} \cdot & & \cdot & & \cdot & & \cdot \\ :\ddot{\text{C}} & \text{H} & \text{H} & \text{H} & \text{H} \\ \cdot & & \cdot & & \cdot & & \cdot \end{array}$$

The first element is the central atom. Arrange other atoms in a North, South, West, and East position.

Because the carbon atom is linked by four bonds, the carbon is *tetravalent*: It has a valence of 4.

# Lewis Dot Structures

Single bonds

represents two  
electrons

Double bonds

represents four  
electrons

Triple Bonds

represents six electrons

Lone pair

# Example: Lewis Dot Structures

**Step 1:** Count valence electrons, adjust for charge of ions

$$1 + 1 + 6 = 8$$
$$\text{H} + \text{H} + \text{O}$$

**Step 2:** Arrange atoms, the first atom is typically the central atom, except hydrogen

**Step 3:** Connect atoms with bonds

**Step 4:** Electrons on the outside first

**Step 5:** Complete octet

**Step 6:** Add charge if needed

$$4 + 5 + 6 + 1 = 16$$
$$\text{C} + \text{N} + \text{O} + e^-$$

# Helpful Hints

1. Remember **simple** Lewis dot structures

one bond, four bonds, two bonds to complete their octet

2. Molecules have **symmetry**

Urea,  $(\text{NH}_2)_2\text{CO}$

$\text{C}_2\text{H}_4$

## 3. Read the formula for order of atom attachment

Acetic acid

# Short Quiz

Which of the following is the correct Lewis structure for  $\text{N}_2\text{O}$ ?

A.

Only 14 VE

B.

C.

Exceeds the Octet

D.

Exceeds the Octet

$\text{N: } 5 \text{ VE} \times 2 = 10$

$\text{O: } 6 \text{ VE} = 6$

total 16 VE

# Example: Lewis Dot Structures

**Step 1:** Count valence electrons, adjust for charge of ions

$$5 + 3(6) + 1 = 24$$
$$\text{N} + 3(\text{O}) + e^-$$

**Step 2:** Arrange atoms, the first atom is typically the central atom, except hydrogen

**Step 3:** Connect atoms with bonds

**Step 4:** Electrons on the outside first

**Step 5:** Complete octet

**Step 6:** Add charge if needed

which one should we use?

# Resonance Structures

Delocalized electrons  
**hop** from one atom to  
another; no discretion  
as long as it's the *same*  
*atom pair*.

Nitrate ion,  $\text{NO}_3^-$

Resonance Structures

Resonance arrows

# Formal Charge

$$\text{Formal Charge} = V - \left( L + \frac{1}{2} B \right)$$

**V**alence electrons

**L**one-pair electrons

**B**onding electrons

The sum of formal charges is equal to the overall charge of the molecule or ion; electrically neutral molecules have a formal charge of zero.

$$\text{O} \quad 6 - (4 + \frac{1}{2} 4) = 0$$

$$\text{Cl} \quad 7 - (6 + \frac{1}{2} 2) = 0$$

$$\text{C} \quad 4 - (0 + \frac{1}{2} 8) = 0$$

# Formal Charge Calculations

$$\text{Formal Charge} = V - \left( L + \frac{1}{2} B \right)$$

Formal charges can predict the most *favourable* Lewis structure:

The structure with the lowest formal charges (absolute value) on each atom is the most favourable (lowest energy) structure.

# Short Quiz

Predict the most *favourable* Lewis structure for  $\text{CNS}^-$ :

A.

B.

# Exceptions to the Octet Rule

Radicals are something you cannot isolate, are very unstable, and are highly reactive.

Hydrogenperoxyl,  
 $\text{HO}_2\cdot$

A biradical

# Piranha Solution

Mixture of  $\text{H}_2\text{SO}_4$  and  $\text{H}_2\text{O}_2$

3:1  $\text{H}_2\text{SO}_4$  conc. and 30 wt%  $\text{H}_2\text{O}_2$

Add  $\text{H}_2\text{O}_2$  to acid very slowly, never in reverse order!

Mixing is extremely exothermic

Prone to explosions

( $T$  too high,  $c_{\text{H}_2\text{O}_2}$  too high, too much contaminant)

Strong oxidizing agent

Will decompose most organic matter

Will hydroxylate most surfaces (adding OH groups)

Easily dissolves fabric and skin

High risk of severe chemical burns

# Exceptions to the Octet Rule

Carbon, nitrogen, oxygen, and fluorine obey the octet rule rigorously. Period 3 and subsequent periods can accommodate more than 8 electrons in its valence shell, up to **18 electrons**.

## Dissociation of $\text{PCl}_5$

(b)  $\text{PCl}_6^-$

Phosphorus pentachloride,  $\text{PCl}_5(s)$

$\text{PCl}_5$

# Exceptions to the Octet Rule

Determine the most stable structure

$$\text{P: } 5 - (0 + \frac{1}{2} \times 8) = +1$$

$$\text{O: } 6 - (6 + \frac{1}{2} \times 1) = -1$$

$$\text{P: } 5 - (0 + \frac{1}{2} \times 10) = 0$$

$$\text{O: } 6 - (4 + \frac{1}{2} \times 4) = 0$$

$$\text{O: } 6 - (6 + \frac{1}{2} \times 1) = -1$$

$$\text{P: } 5 - (0 + \frac{1}{2} \times 12) = -1$$

$$\text{O: } 6 - (4 + \frac{1}{2} \times 4) = 0$$

$$\text{O: } 6 - (6 + \frac{1}{2} \times 1) = -1$$

# Exceptions to the Octet Rule

Cl:  $7-4=+3$

O:  $6-7=(-1)4$

net  $-1$

All atoms have a charge

Cl:  $7-5=+2$

O:  $6-6=0$

O:  $6-7=(-1)3$

net  $-1$

High charge for Cl

Cl:  $7-6=+1$

O:  $6-6=0$

O:  $6-7=(-1)2$

net  $-1$

Charge for Cl and O

Cl:  $7-7=0$

O:  $6-6=0$

O:  $6-7=-1$

net  $-1$

# Short Quiz

Which is the correct Lewis structure for  $\text{BF}_3$ ?

Boron trifluoride,  $\text{BF}_3$

Boron trifluoride,  $\text{BF}_3$

A.

$$\text{F: } 7 - (6 + \frac{1}{2} 2) = 0$$

$$\text{B: } 3 - (0 + \frac{1}{2} 6) = 0$$

B.

$$\text{F: } 7 - (4 + \frac{1}{2} 4) = +1$$

$$\text{B: } 3 - (0 + \frac{1}{2} 8) = -1$$

C. Neither of these

# Ionic or Covalent?

Ionic and covalent bonding are **two extreme bonding models**. Most bonds lie somewhere between purely ionic and purely covalent.

Bonds between a metal and non-metal are present in ionic compounds.

In bonds between non-metals, covalent bonding is a good model.

Can we describe these bonds more accurately by improving the two basic models?

# Correcting the Covalent Model

Both ionic structures **have the same** resonance hybrid energy.

Heterodiatomic molecules **do not** have the same **resonance** hybrid energy.

Experiments show a **small net negative charge** on the Cl atom and **positive** on the H. This is a limitation of formal charge which estimates a **net zero** charge.

Linus Pauling proposed a quantitative **electron-pulling power ability** of an atom in a molecule, called its **electronegativity  $\chi$** .

**Red line** shows **pure** (top) *versus* **actual** (bottom) offset **electron cloud distribution** due to an atom with a greater electronegativity.

# Electronegativity Values

If an atom gives up an electron reluctantly it has **high ionization energy**, and if the electron attaches favourably, it has **high electron affinity**.

# Electronegativity Difference, $\Delta\chi$

Li-F

$$|0.98 - 3.98| = 3.00$$

H-Cl

$$|2.20 - 3.16| = 0.96$$

**Polarization** by small, highly charged cations of larger, nearby anions.

# Bond Energy

Electrons in **double** and **triple bonds** are **not as concentrated (located)** between two atoms as they are in a single bonds.

# Short Quiz

Which molecule has the shortest C—O bond?

Triple bonds are shorter and stronger than double bonds, which are shorter and stronger than single bonds.
